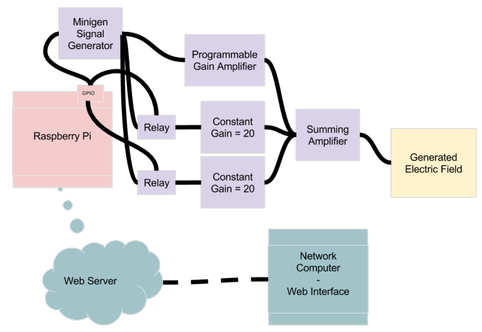
Minnetronix

MINNETRONIX®
THINKING MEDICAL SYSTEMS®

This project is sponsored by Minnetronix, a health care company based in St. Paul, Minnesota, founded in 1996. Minnetronix continues to innovate landscape of health care technology with an emphasis on device development and commercialization of medical technologies. This project is apart of this effort.

Block Diagram



Problem Statement

Our project is part of a larger design to exploit the dielectrophoresis phenomenon for use in medical equipment. There are many medical applications which utilize a method of separation. Centrifuging blood and testing spinal fluids are two examples of such systems. Current testing equipment is expensive therefore a cheaper device utilizing DEP would have a large competitive advantage if constructed.

Dielectrophoresis Phenomenon:

- separate particles in a fluid.
- involves applying an electric field to a fluid.
- field applied over long period of time.
- particle separation depends on electric field characteristics.
- adjusting the voltage and frequency used to generate the field varies its characteristics.

Requirements

This device will need to be capable of operating in a laboratory environment. It is also beneficial if this device is portable. Given these constraints, the proposed solution seeks to create a device which is:

- of small form factor
- having little cost
- capable of separating particles in a fluid utilizing DEP
  - produces 1 to 60_{Vpp}
  - produces 10_{Khz} to 1_{Mhz}

Solution

To fulfill the requirements we propose the use of a Raspberry Pi in combination with a number of circuit components connected to the the GPIO pins present on the Raspberry Pi. The following components will be created and connected to the Raspberry Pi. This will allow for the output of the circuit to be controlled using any computer on the LAN.

- Voltage Control
  - Utilizes three Programmable Gain Amplifiers(PGA)
  - Summing Amplifier to sum the output of PGA's
- Frequency Control
  - Minigen Function Generator
  - Communicates with Raspberry Pi through SPI
- Web Interface
  - Apache 2 web server hosted on Raspberry Pi
  - provides user ability to set voltage and frequency output

Testing

A typical testing environment includes:

- Oscilloscope
- Raspberry Pi
  - Connected for monitor for web interface access
  - Connected to circuit to control Minigen, PGA's
- Multiple breadboards
  - Minigen Function Generator
  - PGA's
  - Summing amplifier

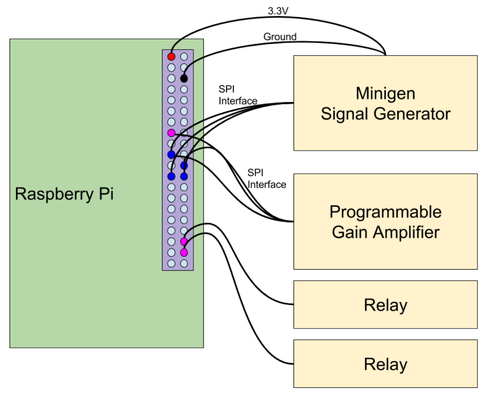
Testing this project involved and iterative process of:

1. Theorize a design
2. Acquire necessary components
3. Construct design
4. Understand problems
5. Return to step 1

Many times we found that designs would not work and thus this process began at the beginning.

Raspberry Pi

The Raspberry Pi acts like a bridge between the user and the electronic circuit. From the perspective of the Pi, there are two interfaces, a web server to interact with the human user and GPIO Pins to interact with the electronic circuit.



Raspberry Pi:

- Approximately 5.6cm x 8.5cm
- Running Linux operating system
- Has 40 General Purpose Input Output (GPIO) pins

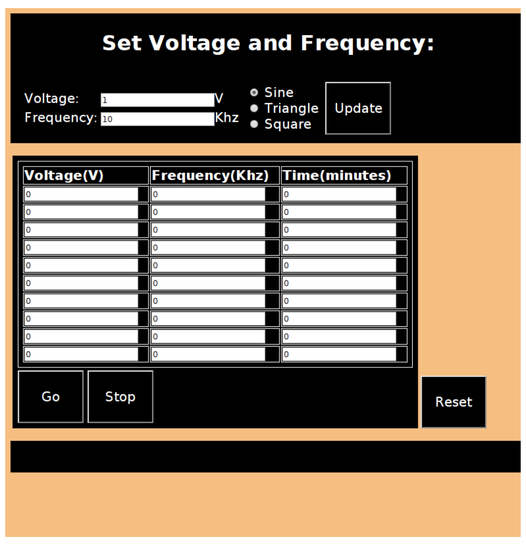
Web Server

- Implemented using Apache 2 web server.
- Updates GPIO state using python and bash scripts

General Purpose Input Output (GPIO) Pins

- Connected to PGA's and Minigen
- SPI communications with Minigen
- Simple 3-bit interactions with PGA's

Web Interface

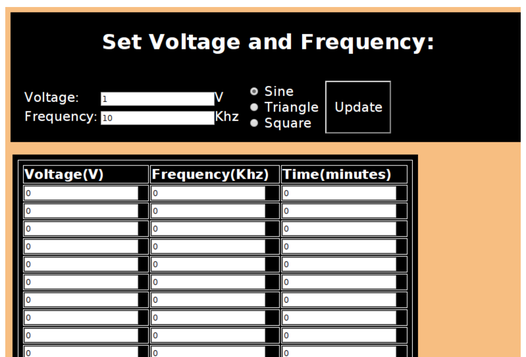


Interface Specifications

- Displayed using Apache 2 web server
- Provides functionalities
  - set voltage
  - set frequency
  - adjust signal type, sine, square, and triangle
  - table allows voltage, frequency for time duration in series
- Implemented using cgi-scripts.

Minigen

The voltage output by the Minigen is not variable. Given that the design specification requires a variable voltage, the voltage needs to be adjusted separately. Accordingly, the output of the Minigen is supplied to the input of the amplifier circuit.



- Variable frequency integrated circuit device
- Interconnections
  - Frequency set over SPI by Raspberry Pi
  - Output supplies PGA's input
- Output waveform
  - can output sine, square, triangle waveforms
  - amplitude $1V_{pp}$
  - from $-0.5V$ to $0.5V$
- Register Interactions
  - 2 frequency registers
    - 28-bit registers
    - one active register controlling output
    - can write inactive register
